# What's Out Tonight? OPTIMIZED FOR $11 / 2$ HOURS AFTER SUNSET <br> Instructions <br> Face North, South, East or <br> UOZINOH ЧҰION <br> FREE 

West, then rotate the chart so your direction is at the bottom. Match the biggest stars on the chart to the brightest stars in the sky. The center of
chart is the top
of the sky.

## Planets

The position of any visible, naked-eye planet is indicated for the 15th of the month. If the planet moves significatnly during a month, other positions will be noted with dates. The ECLIPTIC is the path of the Sun through the sky but the planets and Moon move along it, too. It passes through the constellations of the zodiac.

## 2019 November Planet Notes

Venus (around the 15th), at magnitude -3.9 , sets in the west 1.5 hours after the Sun. Mars, at magnitude 1.8, is in Virgo and rises in the east 2 hours before the Sun. Jupiter, at magnitude - 1.9 is in Ophiuchus and low in the southwest when dark, setting in the west 2 hours after the Sun. Saturn, at magnitude +0.6 , is in Sagittarius and low in the southwest when dark, setting in the west around 8:30.

Distances planets are from the Earth on the 15th of this month: Venus: 140,000,000 miles, Mars: 230,000,000 miles, Jupiter: 562,000,000 miles, Saturn: 985,000,000 miles

## November Notes

The Summer constellations still linger in the west but will retire soon for the winter. The bright stars Deneb, Vega and Altair form the Summer Triangle. Cygnus, the Northern Cross, has, as its bottom end, the beautiful blue/gold double star, Albireo that is visible with a telescope. More eastward is Pegasus and its Great Square with the Andromeda Galaxy closeby. On the eastern horizon is the red star, Aldebaran, an eye of the Bull. Above it is the Pleiades or Seven Sisters, always a favorite. It might look like a little dipper but it is NOT the Little Dipper.

## Clusters, Nebulae \& Galaxies

$\mathrm{ly}=$ Light year, a unit of distance. $1 \mathrm{ly}=6$ trillion miles.
N Alpha Persei Cluster. Distance: 600 ly / Diameter: 31 ly / Mag 1.2 / Spans $3^{\circ}$ / 30 stars.
H Andromeda Galaxy. Companion to our Milky Way Galaxy. Distance: 2,400,000 ly / Diameter: 120,000 ly / Mag 3.5 / Spans $3^{\circ} \times 1^{\circ}$.
H Coathanger Cluster. 10 stars shaped like a bar-type coathanger. It spans $2^{\circ}$ and it stars are 150 ly away.
Double Cluster. Two side-by-side clusters. Distances: 7,200 ly / Diameters: 63 ly / Mag 3.5 / Span $1^{\circ} / 320$ stars total. Best in a telescope.
H Pleiades. And, the "Seven Sisters." Visible with the eyes. Distance: 395 ly / Diameter: 13 ly / Spans $1.8^{\circ}$ / 100 stars.
H IC4665. Cluster. A large sprinkle of stars. Distance: 1,400 ly / Diameter: 17 ly / Mag 4.2 / Spans $40^{\prime} / 30$ stars.
M15. Globular Cluster. Distance: 34,000 ly / Diameter: 122 ly / Mag 6.2 / Spans 13'.
M11. Wild Duck Cluster. Distance: 5,600 ly / Diameter: 23 ly / Mag 5.8 / Spans 14' / 200 stars.
M13. Favorite Globular Cluster. Distance: 21,000 ly / Diameter: 104 ly / Mag 5.8 / Spans 17'.
M22. Beautiful Globular Cluster. Distance: 10,000 ly / Diameter: 70 ly / Mag 5.1 / Spans 24'.
M34. Large Cluster. Distance: 1,400 ly / Diameter: 14 ly / Mag 5.2 / Spans 35 / 60 stars. Try with binoculars, too.
M36. Cluster. Distance: 3,700 ly / Diameter: 13 ly / Mag 6.0 / Spans 12' / 60 stars. Try with binoculars, too.
M37. Cluster. Distance: 4,200 ly / Diameter: 29 ly / Mag 5.6 / Spans 24' / 150 stars. Try with binoculars, too.
M57. Ring Nebula. Planetary Nebula that looks like a smoke ring. Smaller than what you might think. Estimated to be 1 ly in diameter and 2,000 ly away. Mag 9 / Spans 76 " or $1.3^{\prime}$.

## Observing Tips

If possible, observe at a dark location and when the Moon is not bright. A bright Moon will make it more difficult to see the stars and impossible to see clusters, nebulae and galaxies. Only a small telescope at lower magnifications, around 50 x , is required to see the objects listed above. The planets and Moon are best observed with a telescope around 100x. To get a feel for the size of objects, the Moon extends $30^{\prime}$ ( 30 arc minutes). The binocular objects are best with binoculars because these objects are large in size-telescopes have too much magnification.

## Meteor Showers

Southern TAURIDS. Peaks around November 5 with 5 meteors/hour. Northern TAURIDS. Peaks around November 13 with 5 meteors/hour. LEONIDS. Peaks around November 17 with 10 meteors/hour.

## Brightest Stars

Aldebaran. Rising in TAURUS. Magnitude +1 . Distance: 65 ly. Diameter: 36 times the Sun's. Orange Giant.
Altair. In AQUILA. Magnitude +0.9. Distance: 19 ly. Diameter: 1.9 times the Sun's.
Capella. In AURIGA. Magnitude +0.1. Distance: 42 ly. Diameter: 15 times the Sun's. It's actually 4 orbiting stars.
Deneb. In CYGNUS. Magnitude +1.3. Distance: 3200 ly. Diameter: 222 times the Sun's. Blue-White Supergiant.
Fomalhaut. In PISCIS AUSTRINUS. Magnitude 1.2. Distance: 25 ly. Diameter: +1.9 times the Sun's.
Mirach. In ANDROMEDA. Magnitude +2.1 . Distance: 199 ly . Diameter: 89 times the Sun's.
Mirfak. In PERSEUS. Magnitude +1.8. Distance: 592 ly. Diameter: 64 times the Sun's.
Polaris. In URSA MINOR. Magnitude +2 . Distance: 431 ly. 2,400 times brighter than the Sun. Supergiant Star.
Vega. In LYRA. Magnitude +0.02 . Distance: 25 ly. Diameter: 2.4 times the Sun's.

## Mythology

FOR THE CENTRAL CONSTELLATIONS, NORTH TO SOUTH
Arcas and his beautiful mother, Callisto were turned into the Little and Big Bears, URSA MINOR and MAJOR because of jealous Juno, wife of promiscuous Jupiter, who favored Callisto. During an early war between the Titans and Olympians, DRACO, the Dragon was flung to the North and frozen in place by the cold.

King CEPHEUS and Queen CASSIOPEIA ruled Ethiopia. Their daughter ANDROMEDA is being rescued by PERSEUS from the Sea Monster, CETUS. Andromeda was to be sacrificed to Cetus because Cassiopeia boasted of her and her daughter's beauty.

CAPRICORNUS is a "Seagoat," the partially transformed, halfgoat, half-fish body of the god Pan who got scared and hurriedly escaped the monster Typhoon in order to warn Jupiter. The word panic is derived from Pan. AQUARIUS is the Water and Cup Bearer, a servant of the gods. PEGASUS, the Winged Horse is the deliverer of Jupiter's thunderbolts. CYGNUS, the Swan helped Helios find the pieces of his son, having fallen from the chariot that pulls the Sun across the sky. AQUILA is Jupiter's Eagle that carries out tasks. LYRA, the Lyre was invented by Mercury and mastered by Apollo's son, Orpheus whose music had magical powers. PISCES represents Venus and Cupid who changed themselves into Fishes tied with a length of string to stay together and escape the monster Typhoon.

## Moon Phases

D First Quarter. Monday, November 4, 4:23 am, CT
Full Moon. Tuesday, November 12, 7:34 am, CT

- Third or Last Quarter. Tuesday, November 19, 3:11 pm, CT
- New Moon. Tuesday, November 26, 9:06 am, CT

## What's Out Tonight? Sky Chart Supplement

## Clusters, Nebulae \& Galaxies

An Open Cluster is a group of several to hundreds of stars that were born out of the same nebula cloud. A group often forms a pretty pattern. The Pleiades and Praesepe are great examples. Open clusters reside in our Milky Way Galaxy. Our Sun is no longer in its group.

Globular Clusters look like fuzzy balls because they contain tens of thousands stars held together by their mutual gravity. All of the globulars that can be seen in the sky are part of our Milky Way Galaxy, and there are about 200 of them that surround our galaxy like a halo. M22 in SAGITTARIUS is a northern favorite.

A Planetary Nebula is an old term that has nothing to do with the planets. Instead, it is a round or symmetrical nebula that is the shed atmosphere of a dying star. At its center is a white dwarf star. When our Sun dies, it will create a planetary nebula. These objects have diameters of a few light years and are located in our galaxy. The Ring Nebula, M57, in LYRA is a favorite.

A Nebula is a giant hydrogen gas cloud that is located in our galaxy. Within these clouds, concentrations of gas can occur and gravitationally condense to form stars and accompanying planets. A set of stars created by a nebula is known as an Open Cluster. The Orion Nebula, M42 is a favorite.

Galaxies contain billions of stars. All galaxies are beyond our Milky Way Galaxy, where our Sun resides. When you are observing a galaxy, you are looking through our galaxy into the true depths of the universe. The Andromeda Galaxy, M31 can be seen with the naked eye.

## Double Stars

A Double Star is a star that looks like one star but when magnified sufficiently (from 6x to 200x), it separates into two or more stars. Some are very pretty because of contrasting colors. Castor in GEMINI is a favorite and Albireo in CYGNUS is well liked for its blue \& gold colors.

## Moon

Starting from New Moon, the Moon cycles through phases every 29 days, 12 hours, 44 minutes, 3 seconds. It is 2,160 miles in diameter and averages 239,000 miles from Earth. A New Moon is not visible in the sky because the Moon is positioned very close to the Sun. Solar eclipses occur at New Moon. The best time to observe the Moon is during a phase because the craters appear their sharpest near the terminator, the line that separates the lighted side (day side) from the dark side (night side).

## Cycle of Moon Phases

## Planets

The planets are best observed with a telescope using magnifications from 50x to 200x. The five naked-eye planets are Mercury, Venus, Mars, Jupiter and Saturn. Venus is extremely bright and hugs close to the Sun, so you see it for a short time in the west after sunset or in the east before sunrise. Jupiter can be out all night and always outshines any star. Everyone enjoys its 4 Galilean moons and cloud bands, easily visible at 50x. It is possible to see the moons with well-focused binoculars. Saturn is everyone's favorite because of its beautiful rings. Mars gets close to Earth about every 2 years at which time it is very bright. This is the best time to observe it but you need higher magnifiAt
arm's
length...

The width of a bowl.

|  |  | Diameter In Miles | Rotation Its Day | Distance from Sun In Miles | Revolution Its Year |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Q | SUN | 865,000 | 30 days | - | - |
| One thumb | MERCURY | 3,032 | 59 days | 36,000,000 | 88 days |
| wiuth is 4 Moon | VENUS | 7,521 | 243 days | 67,000,000 | 225 days |
|  | EARTH | 7,926 | 24 hours | 93,000,000 | 365 days |
|  | MARS | 4,228 | 24.6 hours | 142,000,000 | 687 days |
|  | JUPITER | 88,844 | 9.8 hours | 484,000,000 | 11.8 years |
|  | SATURN | 74,900 | 10.2 hours | 887,000,000 | 29 years |

|  | NEPTUNE | 30,777 | 19.2 hours | 2,800,000,000 | 164 years |
| ¢ | PLUTO | 1,433 | 6.4 days | 3,700,000,000 | 248 years |

## Light Year (ly) \& Nearest Stars

A Light Year (ly) is a unit of length and is equal to the distance light travels in one year. Since light moves at the speed of 186,282 miles a second, one light year is nearly 6 trillion miles long. The closest nighttime star visible to the naked eye is Alpha ( $\alpha$ ) Centauri in the constellation CENTARUS. Alpha Centauri shines brightly at magnitude -0.01 and is just 4.4 light years away. The very closest star dasisu is Proxima in CENTARUS at just 4.22 ly away. It is $:$ or to faint to see with the eyes because it shines at .. magnitude +11 . The second closest star visible to the naked eye is Sirius at 8.6 ly followed by Epsilon ( $\varepsilon$ ) Eridani at 10.5 ly and Procyon at 11.4 ly. There are several stars closer than these three but they are too faint to be seen with the naked eye.
cations around 150x to see the surface coloration.
